

Glycogen Degradation

Chapter 24, Stryer Short Course

Glucose Metabolism Overview

- Gluconeogenesis
- **Glycogen metabolism**
- Pentose Phosphate Pathway

Glycogen

- Storage molecule
- Primer necessary
- Very large!
- Multiple ends allow for quick synthesis and degradation

Four Degradation Enzymes

- Two enzyme debranching process
- Glycogen phosphorylase
- phophoglucomutase

Chemistry of Degradation

- Glycogen phosphorylase
- Key Regulation site
- Inorganic phosphate as a nucleophile
- Splits $\alpha(1\rightarrow4)$ bonds
- Remake G-1-P with no ATP cost

Debranching

- Transfer branch
- $\alpha(1\rightarrow6)$ glycosidase

Figure 24.3

Mutase

- G-1-P to G-6-P with no energy expenditure
- Central metabolite
 - Muscle: glycolysis, pentose phosphate pathway
 - Liver: glycolysis, PPP, free glucose for blood

Key Regulatory Enzymes

Glycogen Phosphorylase

- Dimeric
- Allosteric control
- Hormone level control
- Tissue isozymes
 - Muscle: Purpose is to release fuel for itself
 - Liver: Purpose is to release fuel for whole organism

Covalent Modification

- Phosphorylase a
 - Phosphorylated
 - “usually active”
 - Default liver isozyme
- Phosphorylase b
 - Dephosphorylated
 - “usually inactive”
 - Default muscle enzyme

Liver Activity

- Physiological purpose: release of glucose
 - Default setting
- High glucose concentration favors T state in Phosphorylase a
- Turns off active glycogen degradation

Muscle Activity

- Physiological purpose: conserve glycogen until a burst is needed
- Detection of energy charge
 - AMP shifts equilibrium to relaxed state

Muscle Fiber

- Type I: Slow twitch
 - For endurance
 - use fats for aerobic catabolism
- Type IIb: Fast twitch
 - Burst of strength
 - Glycogen as main fuel source (anaerobic)
- Type IIa: Intermediate

Hormone Regulation

- Interconversion of “usually active” and “usually inactive” phosphorylase is hormone mediated
- Activation by glucagon and epinephrine

Figure 24.10 Biochemistry: A Short Course, Third Edition © 2013 Macmillan Education

Signal Transduction

- Activation of cascade leads to active degradation of glycogen
- Epinephrine affects liver through IP₃ pathway

Regulating regulators

- Influx of calcium in active muscle partially activates kinase
- Hormone response fully activates

Glycogen Storage Diseases

Type	Enzyme Deficiency
→ I	Glucose-6-phosphatase
→ II	α-1,4-Glucosidase
→ III	Amylo-1,6-glucosidase (debranching enzyme)
→ IV	Amylo-(1,4 → 1,6)-transglycosylase (branching enzyme)
→ V	Muscle glycogen phosphorylase
→ VI	Liver glycogen phosphorylase
→ VII	Phosphofructokinase
→ VIII, IX, X	Phosphorylase kinase
→ XI	GLUT2 transporter
→ 0	Glycogen synthase

Many disrupt glycogen breakdown in muscle and/or liver (hypoglycemia, enlarged liver, muscle cramps...)
